Battery cabinet zero drift current is too large

Overview

If zero-drift current is positive and persistent, it may falsely raise SOC, tricking the system into thinking the battery is more charged than it actually is—possibly cutting off charging prematurely. Conversely, negative drift may lead to underestimated SOC, triggering early. Zero-drift current refers to the false current signal generated in an amplifier circuit when there is zero input current, but due to factors like temperature changes or power supply instability, the static operating point of the amplifier shifts. This shift gets amplified and causes the output to. This phenomenon, known as SoC drift, can affect your system's performance and even its safety. An incorrect SoC reading can lead to unexpected shutdowns or, in worse cases, damage your battery. For safety reasons and durability of the batteries I don't want to exceed the charge current for more than 40A even if the cells are capable of being charged with more power, but anyway. In conjunction with DVCC this works very well, BUT if. Load-cell bridge: big zero drift on 9 V, and when I power it from Arduino 5 V it overheats - what am I doing wrong?

I have a load-cell bridge from a scale. Have you verified the actual load with a clamp-on ammeter or an external shunt?

We had inaccurate current readouts with our Daly 4S 200a Smart BMS. We calibrated both "Work" and "Zero" current using Sinowealth (Windows desktop app). I would assume the same could be done with the 8S Daly. Either. Have you ever wondered why battery cabinet current limits account for 43% of thermal runaway incidents in grid-scale storage systems?

As renewable integration accelerates globally, the hidden challenges of current regulation in battery enclosures are reshaping engineering priorities.

Load-cell bridge: big zero drift on 9 V, and when I power it from

Problem: zero drifts a lot. I think it's because the 9 V battery and Arduino 5 V change differently (not synchronized) over time, so the ratio V_{sig}/V_{ref} in Arduino ADC changes and zero drifts.

Battery cabinet discharge current is too large

Overdischarge of the battery may bring catastrophic damage to the battery consequences, especially large current over-discharge, or repeated over-discharge will have a greater impact on the battery.
