# **Double glass component bonding**

## Overview

---

This blog post explores the most effective methods for permanently bonding glass to glass, focusing on the sophisticated approach of UV curing adhesives and providing practical insights for manufacturers and industry professionals. Glass bonding is the specialized process of securely joining two pieces of glass, or glass to dissimilar materials, to form a strong, sealed connection. Glass is rigid, non-porous, and has a low-energy surface that naturally resists adhesion. They are characterised by the fact that they cure not because a substance such as a solvent or water evaporates, but because of a chemical reaction. It is absolutely essential for the two required components to be. This paper investigates the properties of different bonding processes available and presents solutions for bonding plain glass wafers, with investigation into using the same process for bonding glass with microfluidic channels etched in them. The Borofloat 33 wafers went through a two-step process with a pre-bond and high-temperature bond in a furnace. The pre-bond process included.

## Double glass component bonding

### Glass substrate fabrication using hybrid bonding

In one aspect, the present disclosure is directed to methods for making glass substrates, suitable for mounting integrated circuit devices, which utilize multiple thin glass panels that are
