Photovoltaic panel withstand voltage insulation test

Overview

The test measures the insulation resistance between the conductors and ground. The PV industry commonly uses the test before energizing the cables during project commissioning, during regularly scheduled maintenance, and as a tool for diagnosing system performance. Megohm or insulation resistance (IR) tests validate the insulating properties of conductors used in electrical installations. A conductor with good insulation will have high resistance, and poor insulation will have low resistance. Solar panels endure harsh conditions—UV exposure, temperature extremes, and moisture—all of which degrade insulation over time. Faulty insulation can lead to ground faults, fires, or system downtime, risking both safety and ROI. Specifiers need to consider the following factors when selecting an IMD for use in a PV array. New insulation will have some leakage current, albeit small. This leakage current will flow from the conductor to the outside of the cable, where it needs to be connected.

Photovoltaic panel withstand voltage insulation test

Insulation Resistance Measurement for the Safety of Solar PV

The purpose of the dielectric withstand (hi-pot) test is to determine whether the insulation from the primary circuit to grounded or accessible parts has sufficient electric strength to withstand the normal
